Two-Stage Certification Results for the GKW Transfer Operator

Isaia Nisoli

16 February 2026

1 Certified spectral enclosures for the Gauss–Kuzmin–Wirsing operator

This section reports a fully *certified* numerical enclosure of the leading part of the spectrum of the Gauss–Kuzmin–Wirsing (GKW) transfer operator. The analytic setting (Hardy spaces, boundedness/compactness, and the explicit truncation error $\|L - L_K\| \le \varepsilon_K$) is established in the previous section; here we focus on the numerical pipeline and the concrete constants used in the experiment.

Our certification follows the abstract "resolvent bridge" strategy: we first produce resolvent bounds and spectral separation certificates for a finite-dimensional discretization, and then lift them to the infinite-dimensional operator using the tail bound ε_K. To reduce computational cost, we use a two-stage (coarse–fine) workflow: a coarse discretization isolates spectral clusters and provides initial resolvent bounds, which are then propagated and sharpened at a finer level.

1.1 Refined bounds for C_2 by splitting

Remark 1 (Refined bounds for C_2 by splitting)**.** *Write*

$$\frac{\sqrt{2n+1}}{(n-\frac{1}{2})^2} = \sqrt{\frac{2n+1}{n-\frac{1}{2}}}\,(n-\tfrac{1}{2})^{-3/2}.$$

For any $N \ge 1$ we have

$$\sup_{n\ge N} \frac{2n+1}{n-\frac{1}{2}} = 2 + \frac{2}{N-\frac{1}{2}},$$

hence, splitting the series at N yields

$$\|L\|_{H^2(D_1)\to H^2(D_{3/2})} \le \sum_{n=1}^{N-1} \frac{\sqrt{2n+1}}{(n-\frac{1}{2})^2} + \sqrt{2+\frac{2}{N-\frac{1}{2}}} \sum_{n\ge N} (n-\tfrac{1}{2})^{-3/2}.$$

The tail is expressed via the Hurwitz zeta function:

$$\sum_{n\ge N} (n-\tfrac{1}{2})^{-3/2} = \zeta\big(\tfrac{3}{2},\, N-\tfrac{1}{2}\big)\,.$$

Table 1 reports rigorous upper bounds for C_2 obtained from this splitting strategy, computed with `Arb`*; the maximum enclosure radius is bounded by 5×10^{-34}.*

N	$C_2(N)$
1	11.7000807086
2	10.4849507042
3	10.2709840576
4	10.1907129342

1000	10.0581271764
10000	10.0580982915

Table 1: Refined rigorous upper bounds for C_2 as a function of the splitting parameter N.

1.2 Computational environment and parameter choices

Computational environment

All computations were performed on a single workstation with the following specifications:

- **Processor:** AMD Ryzen 9 5950X (16 cores, 32 threads via SMT, base 3.4 GHz / boost 4.9 GHz)
- **Memory:** 128 GB DDR4
- **OS:** Ubuntu 22.04.5 LTS (kernel 6.8.0-79)
- **Software:** Julia 1.12.4 with 32 threads; packages: GKWExperiments.jl, BallArithmetic.jl, GenericSchur.jl, ArbNumerics.jl

Table 4: Two-stage certification results for the first 50 eigenvalues of the GKW operator ($s = 1$). The column $\alpha_1 = \varepsilon_{K_{\text{low}}} \cdot \|R_{A_{K_{\text{low}}}}(z)\|$ is the small-gain factor on the excluding circle Γ_j. All 50 eigenvalues satisfy $\alpha_1 < 1$, proving simplicity and giving certified resolvent bounds. For $j = 1$–15, CertifScripts circle certification on the full A_{48}; for $j = 16$–50, block Schur at $K = 256$ with CertifScripts on T_{22}.

Table 2: Computational timings for each stage of the certification pipeline. Timings with "(cached)" indicate that the BallMatrix or Schur decomposition was loaded from a previous run.

Phase	Description	Wall time
Script 1: Resolvent certification (`full_certification_50eigs.jl`)		
1a	CertifScripts on full A_{48} ($j = 1$–15)	<1 min
1b	Block Schur + CertifScripts on T_{22}, $K = 256$ ($j = 21$–50)	<1 min
1c	Fallback: block Schur + CertifScripts, $K = 256$ ($j = 16$–20)	~ 2 min
2	Transfer bridge + projector errors	<1 min
3	Tail resolvent on separating circle	~ 32 s
Total		~ 2.5 min
Script 2: NK + spectral coefficients (`spectral_data_50eigs.jl`)		
Schur	BigFloat Schur, $K = 256$, 512-bit (GenericSchur)	~ 20 min
NK	Newton–Kantorovich (35/50 pass)	~ 30 min
ordschur	$\ell_j(\mathbf{1})$ via ordschur + Sylvester (50 eigs)	~ 2 min
Script 3: $K = 512$ spectral (`bigfloat_spectral_K512.jl`)		
Build	ArbNumerics matrix, $K = 512$, 1024-bit	3.0 min
Schur	513×513 GenericSchur at 1024-bit	~ 1 hr
Quality	Residual + orthogonality norms	~ 8 min
ordschur	$50\times$ ordschur + Sylvester + perturbation	~ 2 min
Total		~ 1.2 hr

Table 5: Certified resolvent bounds. $\|R_{A_{K_{\text{low}}}}\|$ is the resolvent of the finite-dimensional Galerkin matrix on the excluding circle Γ_j, certified via resolvent sampling (Phase 1a) or Schur direct method (Phase 1b/c). $M_\infty = \|R_{L_r}(z)\|$ is the certified resolvent bound for the infinite-dimensional operator via Neumann perturbation: $M_\infty \leq \|R_{A_{K_{\text{low}}}}\|/(1-\alpha_1)$. The transfer columns give $\|R_{A_{K_{\text{high}}}}\|$ via reverse perturbation at $K_{\text{high}} = 256$.

j	K_{low}	$\|R_{A_{K_{\text{low}}}}\|$	$M_\infty = \|R_{L_r}\|$	α_{high}	$\|R_{A_{K_{\text{high}}}}\|$

Theorem 1 (Rigorous spectral certification of the GKW operator)**.** *Let $L_r : H^2(D_r) \to H^2(D_r)$ be the GKW transfer operator for $s = 1$, $r = 1$. The first 50 eigenvalues $\lambda_1, \ldots, \lambda_{50}$ (ordered by decreasing modulus) are simple: all 50 excluding circles $\Gamma_j \subset \rho(L_r)$ are certified via the two-stage*

Table 3: Two-stage certification parameters

Parameter	Value
K_{low}	48 (eigenvalues 1–15), 256 (eigenvalues 16–50)

35. $\lambda_{35}^* \in B(2.810825e-15,\ 5.55\times 10^{-30}),\quad \|P_{L_r}(\Gamma_{35}) - P_{A_{256}}(\Gamma_{35})\| \le 2.96\times 10^{-3}$

Here $B(c,r)$ denotes the closed ball $\{z\in\mathbb{C} : |z-c|\le r\}$, and Γ_j is the excluding circle of radius listed in Table 4 centered at $\hat{\lambda}_j$. Eigenvalues 36–50 are certified to be simple (resolvent is finite on Γ_j) but the NK radius is infinite at $K=256$; at $K=512$ (1024-bit precision), all 50 eigenvalues have finite NK-type enclosures (Table 6).

Method. *For $j=1,\dots,15$, Stage 1 certifies that $\Gamma_j\subset\rho(L_r)$ by verifying $\alpha_1=\varepsilon_{K_{\mathrm{low}}}\cdot\|R_{A_{K_{\mathrm{low}}}}(z)\|_{(\Gamma_j)}<1$ via resolvent sampling with 256 points on Γ_j, using the Galerkin matrix of size $K_{\mathrm{low}}+1=49$. For $j=16,\dots,50$, the Schur direct method at $K=256$ provides resolvent certification via block triangular structure of the certified Schur form, without resolvent sampling. Stage 2 applies a Newton–Kantorovich defect-based argument at $K_{\mathrm{high}}=256$ ($\varepsilon_{256}\approx 5.59\times 10^{-45}$) to obtain tight eigenpair enclosures. The Riesz projector error is bounded via $\|P_{L_r}-P_{A_{K_{\mathrm{high}}}}\|\le\frac{|\Gamma_j|}{2\pi}\cdot\frac{\|R_{A_{K_{\mathrm{high}}}}\|^2\cdot\varepsilon_{K_{\mathrm{high}}}}{1-\varepsilon_{K_{\mathrm{high}}}\cdot\|R_{A_{K_{\mathrm{high}}}}\|}$, where $\|R_{A_{K_{\mathrm{high}}}}\|$ is obtained from M_∞ by reverse perturbation. The tail resolvent on the separating circle gives $\|R_{L_r}\|_{(\Gamma_{\mathrm{tail}})}\le 6.06\times 10^{41}$ with effective spectral radius $\rho_{\mathrm{tail}}\approx 1.01\times 10^{-21}$. All scalar bounds use directed rounding to ensure rigor.*

Rigorous Spectral Expansion

Since all 50 eigenvalues are certified to be simple (Theorem 1), each eigenvalue λ_j has a rank-one Riesz projector $P_j = v_j \otimes \ell_j$, where v_j is the right eigenvector ($\|v_j\|_2 = 1$) and ℓ_j the left (dual) eigenvector, normalized so that $\ell_j(v_j) = 1$. The spectral expansion of L^n applied to the constant function $\mathbf{1}$ is

$$L^n \mathbf{1} = \sum_{j=1}^{N} \lambda_j^n \, \ell_j(\mathbf{1}) \, v_j + R_N(n), \tag{1}$$

where $\ell_j(\mathbf{1}) = \langle P_j(\mathbf{1}), v_j \rangle$ is the spectral coefficient and $R_N(n)$ is bounded by $|\lambda_{N+1}|^n$ times the tail projector norm.

Computation of $\ell_j(\mathbf{1})$ at $K = 256$. The GKW matrix A_{256} is built in high-precision arithmetic (ArbNumerics, 512 bits) and rigorously converted to a `BallMatrix` with BigFloat centers. A direct BigFloat Schur decomposition $A = QTQ'$ is computed via `GenericSchur.jl`, achieving residual $\|A - QTQ'\|_2 \le 2.82 \times 10^{-24}$ (before refinement) and orthogonality defect $\|Q'Q - I\|_2 \le 1.75 \times 10^{-153}$. The total Schur enclosure error is $\|E\| = \|A_{\text{true}} - QTQ'\|_2 \le 4.96 \times 10^{-154}$. For each eigenvalue λ_j, a BigFloat `ordschur` reorders the target eigenvalue to position $(1,1)$. The reordering is realized as a product of unitary Givens rotations ($\widehat{U}$); in finite precision we track (i) the orthogonality defect $\|I - \widehat{U}^* \widehat{U}\|_2$ and (ii) the reconstruction error $\|T - \widehat{U}\,\widetilde{T}\,\widehat{U}^*\|_2$. The left eigenvector functional ℓ_j is then recovered via a Sylvester solve; the resulting projector and resolvent bounds are transported from $\widetilde{T}$ back to (T, A) by a two-step perturbation estimate. More precisely, with $T = \left[\begin{smallmatrix} \lambda_j & T_{12} \\ 0 & T_{22} \end{smallmatrix}\right]$, the solution $z_0 = (T_{22} - \lambda_j I)^{-1} w_{\text{rest}}$ gives $\ell_j(\mathbf{1}) = w_1 - T_{12} \cdot z_0$, where $w = Q_{1,:}$ is the first row of the reordered Q. The certified error δ accounts for the Sylvester residual, the Schur perturbation $\|E\|$, and the NK eigenvector error: $\delta \le \delta_{\text{Sylv}} + \delta_{\text{pert}} + \delta_{\text{NK}}$. All 35 coefficients ($j = 1, \ldots, 35$) are certified with $|\ell_j(\mathbf{1})| > \delta$ at $K = 256$.

Computation of $\ell_j(\mathbf{1})$ at $K = 512$. At $K = 512$ with 1024-bit precision (≈ 308 decimal digits), the Schur enclosure error drops to $\|E\| \le 8.64 \times 10^{-163}$, and all 50 coefficients are sign-certified with radii at the 10^{-128}–10^{-162} level. This provides independent confirmation of the $K = 256$ results and extends certification to eigenvalues 36–50.

Table 6: Rigorous spectral expansion coefficients $\ell_j(\mathbf{1})$ for the first 50 eigenvalues. Computed via BigFloat Schur decomposition (GenericSchur.jl) with Sylvester-based Riesz projector recovery. At $K = 256$ (512-bit precision), $\|E\| \le 4.96 \times 10^{-154}$; at $K = 512$ (1024-bit precision), $\|E\| \le 8.64 \times 10^{-163}$. All 50 coefficients are sign-certified at $K = 512$. At $K = 256$, the first 35 are certified; eigenvalues 36–50 require $K = 512$.

Eigenfunctions

The following figures show the eigenfunctions $v_j(x)$ evaluated on $[0.01, 0.99]$ in the shifted monomial basis $\{(x-1)^k\}_{k=0}^{K}$, with $K = 512$ (1024-bit precision). Each batch of 10 eigenfunctions is plotted in a 2×5 grid.

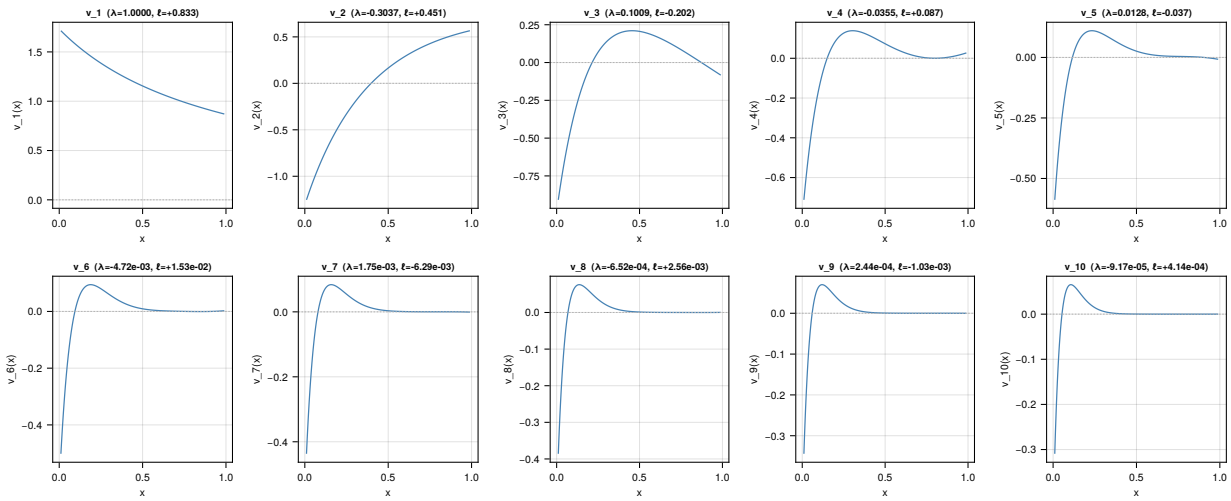

Figure 1: Eigenfunctions $v_1, \ldots, v_{10}$. The invariant density v_1 (top left) is positive; higher eigenfunctions oscillate with increasing frequency. Each panel shows λ_j and $\ell_j(\mathbf{1})$.

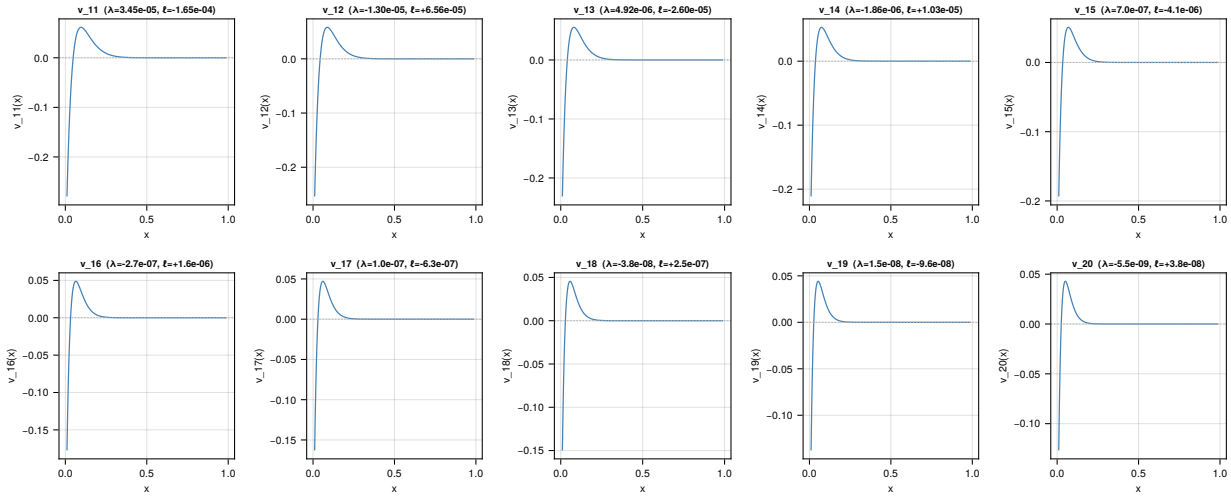

Figure 2: Eigenfunctions $v_{11}, \ldots, v_{20}$. Eigenvalues $|\lambda_j| \sim 10^{-5}$–10^{-9}; these modes decay rapidly under iteration.

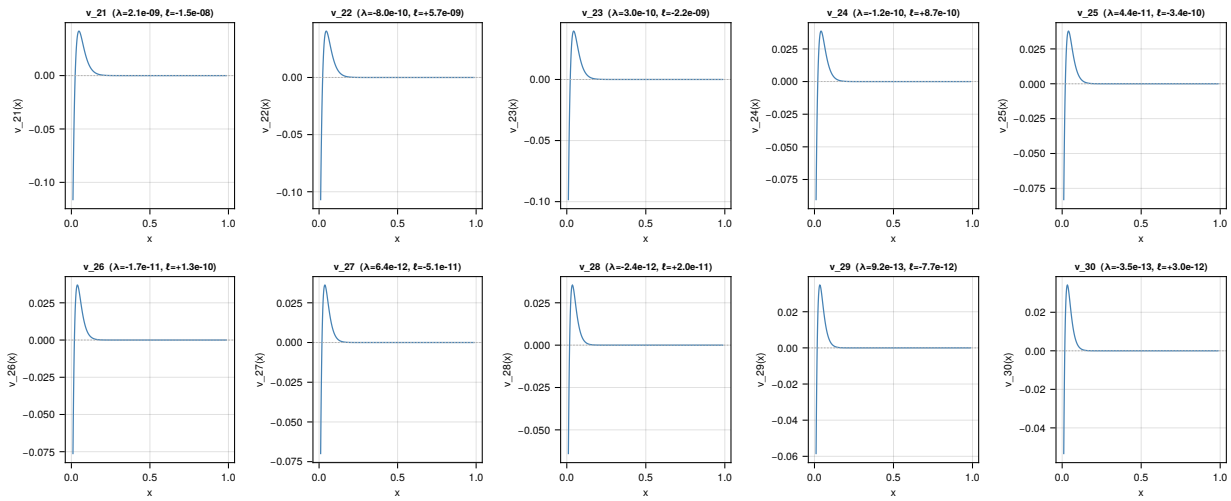

Figure 3: Eigenfunctions $v_{21}, \ldots, v_{30}$. Eigenvalues $|\lambda_j| \sim 10^{-9}$–10^{-13}.

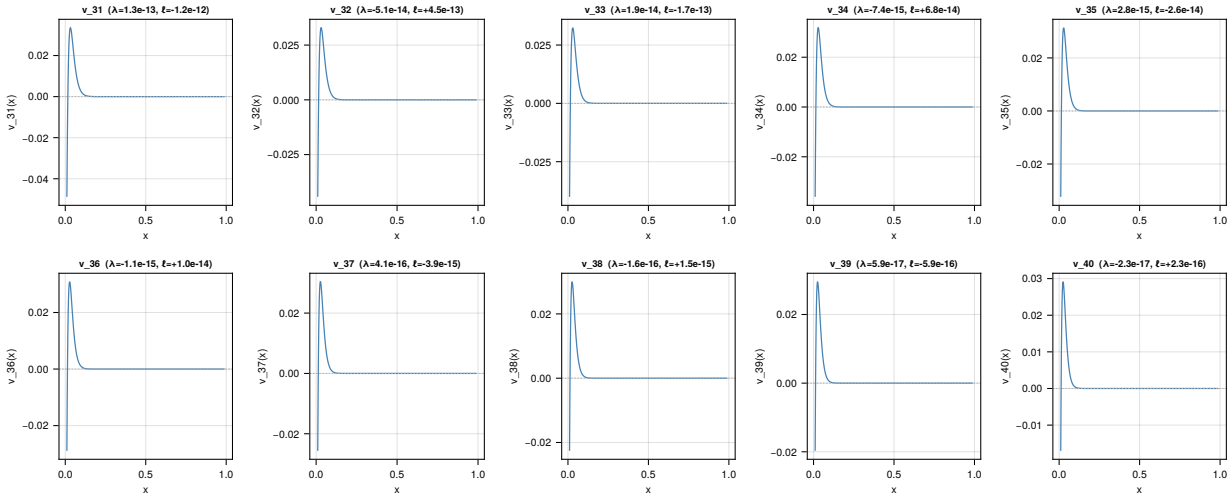

Figure 4: Eigenfunctions $v_{31}, \ldots, v_{40}$. Eigenvalues $|\lambda_j| \sim 10^{-13}$–$10^{-17}$.

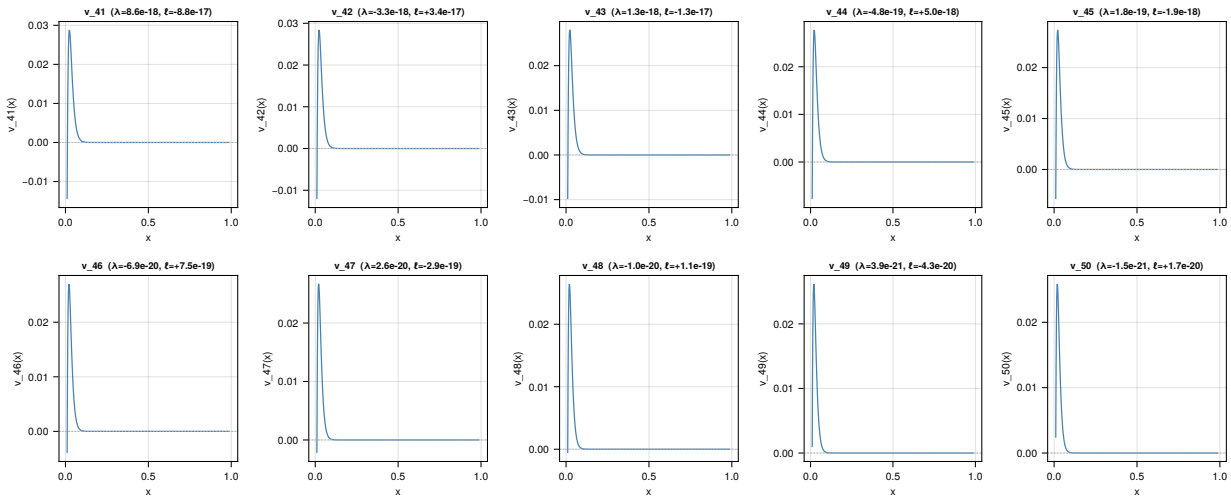

Figure 5: Eigenfunctions $v_{41}, \ldots, v_{50}$. Eigenvalues $|\lambda_j| \sim 10^{-17}$–$10^{-21}$.

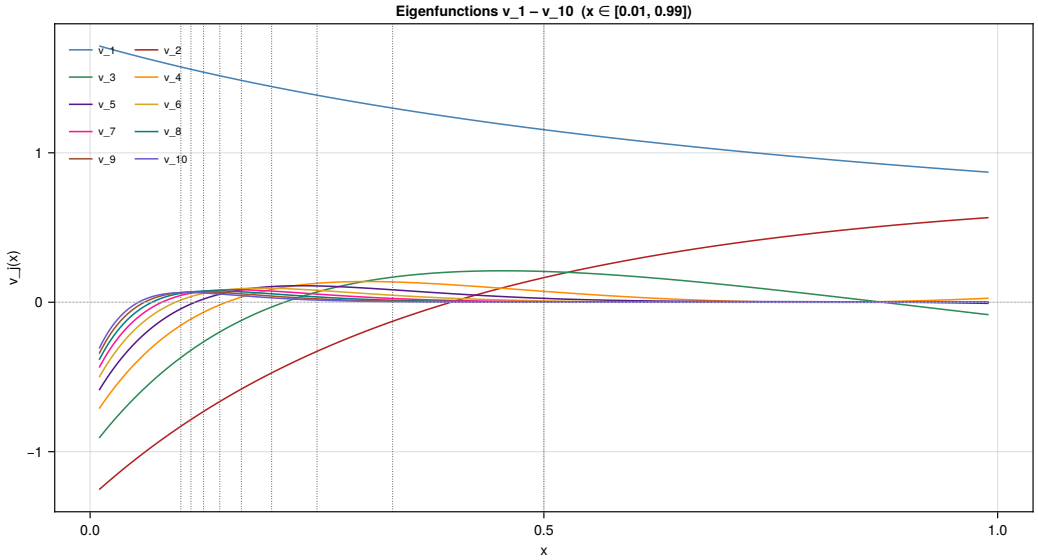

Figure 6: Eigenfunctions $v_1, \ldots, v_{10}$ overlaid with Markov partition (vertical lines at $x = 1/n$, $n = 2, \ldots, 10$).

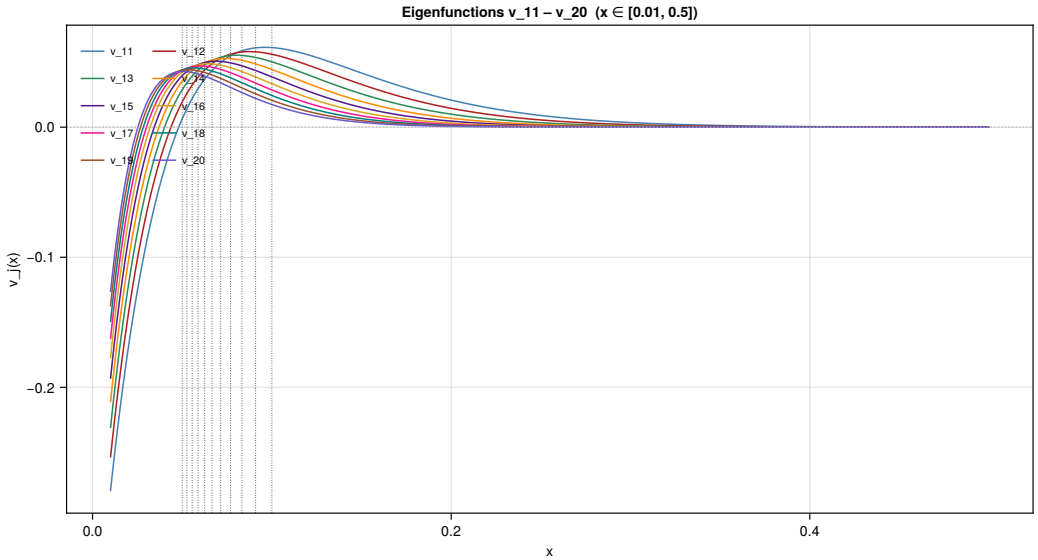

Figure 7: Eigenfunctions $v_{11}, \ldots, v_{20}$ overlaid with Markov partition.

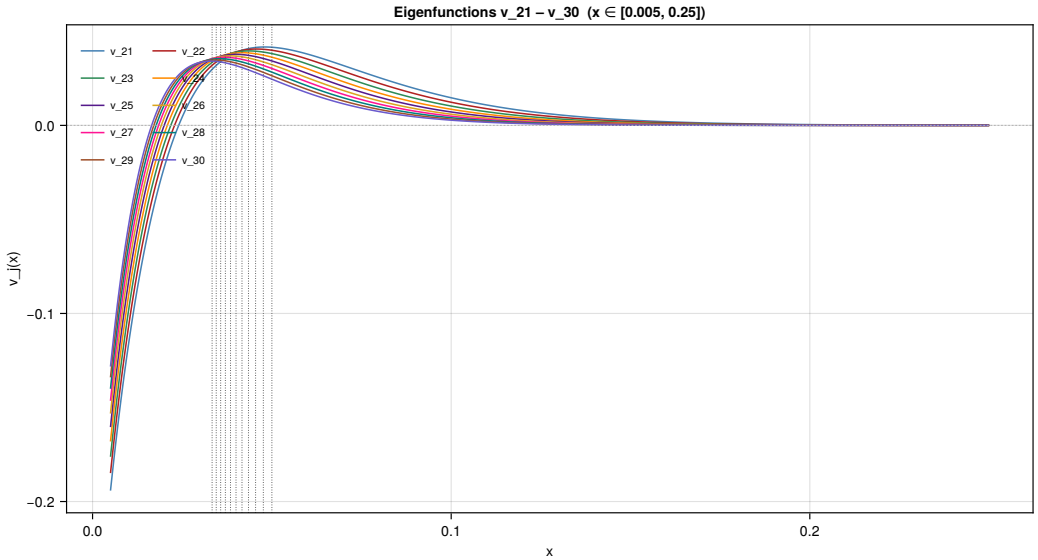

Figure 8: Eigenfunctions $v_{21}, \ldots, v_{30}$ overlaid with Markov partition.

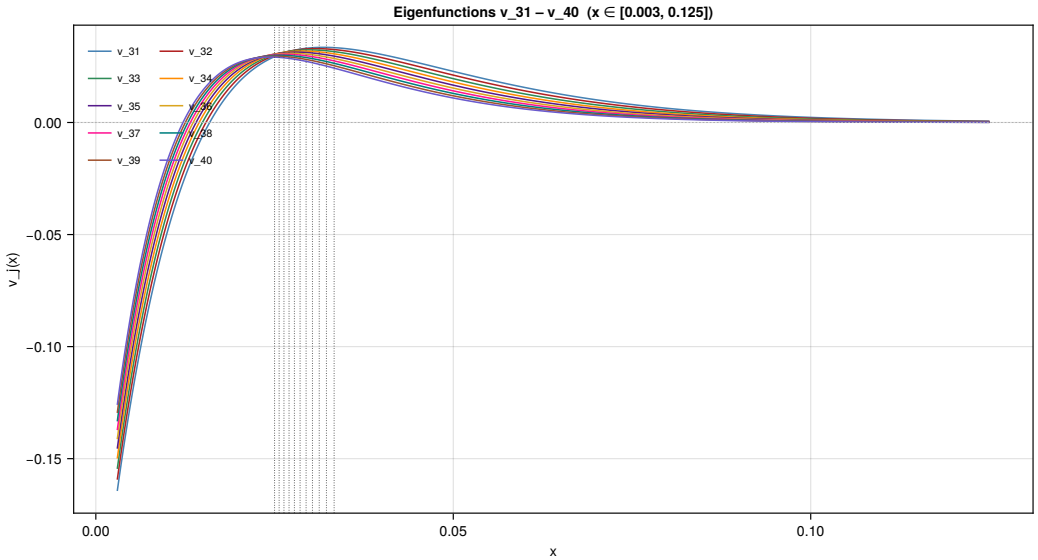

Figure 9: Eigenfunctions $v_{31}, \ldots, v_{40}$ overlaid with Markov partition.

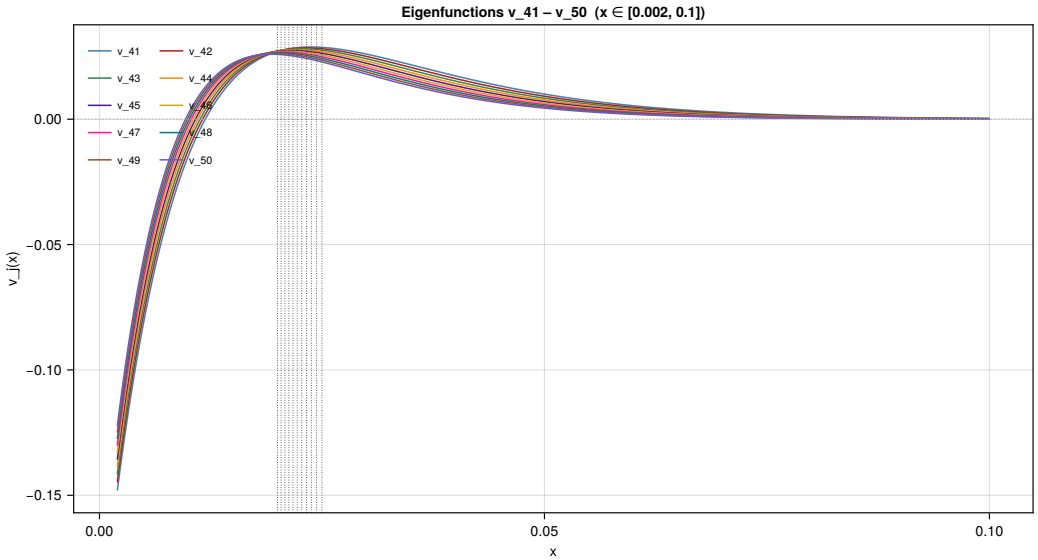

Figure 10: Eigenfunctions $v_{41}, \ldots, v_{50}$ overlaid with Markov partition.

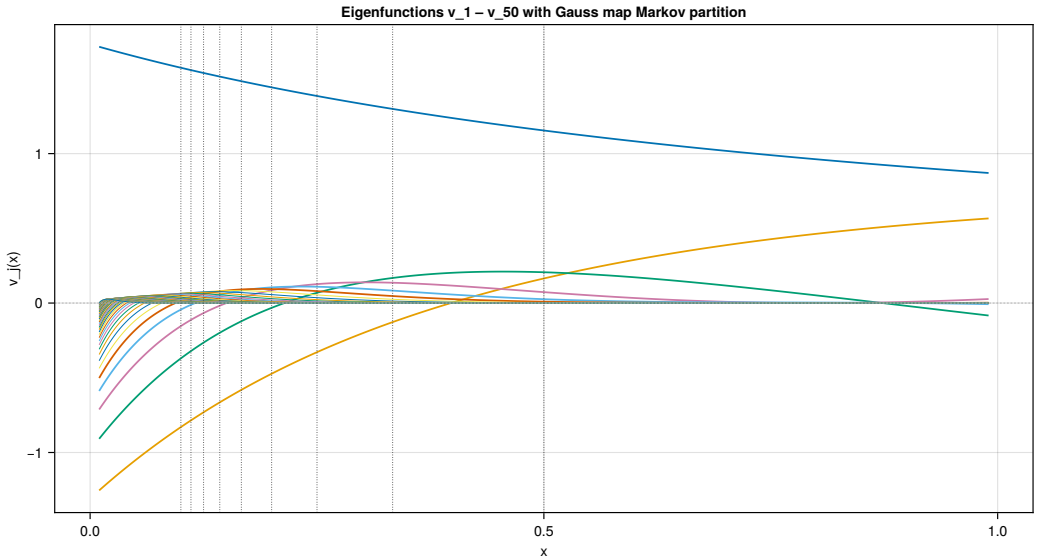

Figure 11: All 50 eigenfunctions overlaid, with Gauss map Markov partition (vertical dotted lines at $x = 1/n$, $n = 2, \ldots, 10$).

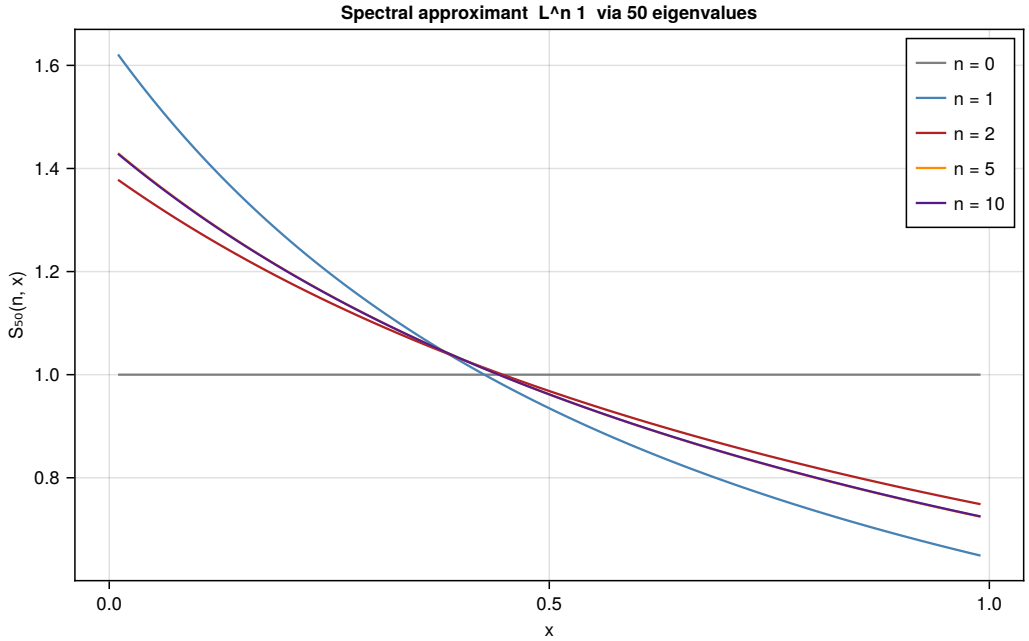

Figure 12: Spectral approximant $S_{50}(n, x) = \sum_{j=1}^{50} \lambda_j^n \, \ell_j(\mathbf{1}) \, v_j(x)$ for $n = 0, 1, 2, 5, 10$. At $n = 0$ the sum reconstructs the constant function $\mathbf{1}$; at $n = 1$ it approximates the transfer operator applied to $\mathbf{1}$; for large n it converges to $\lambda_1^n \, \ell_1(\mathbf{1}) \, v_1(x)$.

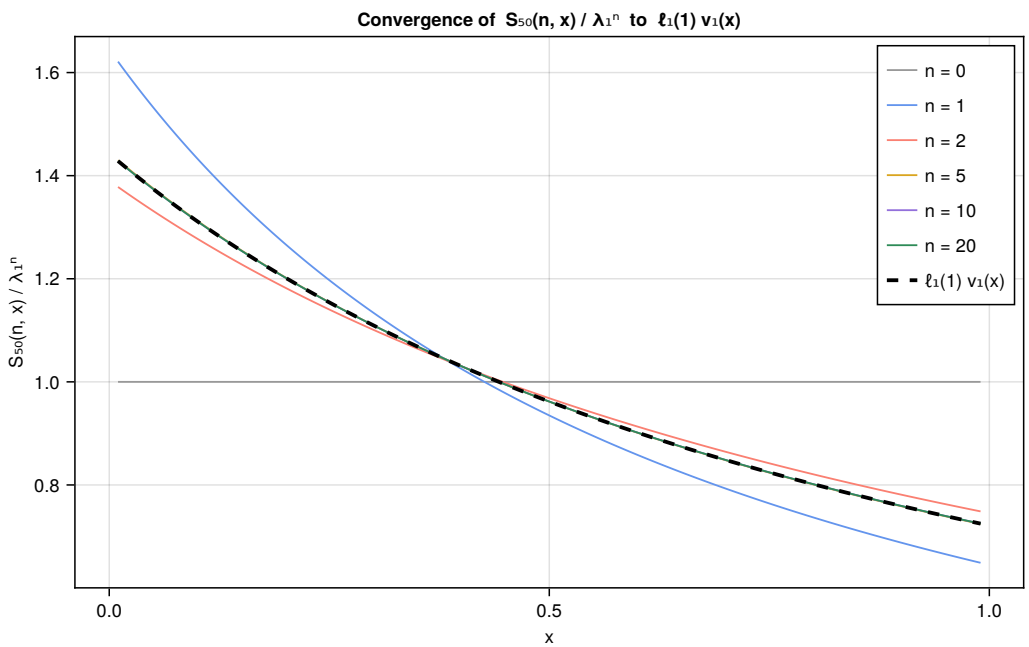

Figure 13: Convergence of $S_{50}(n,x)/\lambda_1^n$ to the invariant density $\ell_1(\mathbf{1})\, v_1(x)$ (dashed black). The spectral gap $|\lambda_2/\lambda_1| \approx 0.304$ governs the rate of convergence.

Eigenvector Coefficients $[v_j]_k$

The following tables list the first 50 coefficients of each unit-norm eigenvector v_j in the shifted monomial basis $\{(w-1)^k\}_{k=0}^{K}$. The ℓ^2 error $\|\hat{v}_j - v_j\|_2 \leq \delta_j$ shown for each eigenvector is controlled by the Schur orthogonality defect and the reconstruction error from the ordschur + Sylvester pipeline (see Tables 6 and **??**). Eigenvectors at $K = 512$ (1024-bit precision) achieve radii $\sim 10^{-162}$–10^{-128}.

Tail Bound for the Spectral Remainder

The spectral expansion (1) has remainder

$$R_N(n) \;=\; L^n\mathbf{1} - \sum_{j=1}^{N} \lambda_j^n\, \ell_j(\mathbf{1})\, v_j.$$

We bound $\|R_N(n)\|_2$ by combining the Cauchy integral formula with a direct computation of the *tail projection* $Q_N\mathbf{1}$, where $Q_N = I - \sum_{j=1}^{N} P_j$ is the tail spectral projector.

Factored tail bound. Since Q_N commutes with L_r (Riesz projectors commute with the operator, regardless of normality), we have the factorization

$$R_N(n) = Q_N L^n\mathbf{1} = (Q_N L^n)(Q_N\mathbf{1}),$$

using only $Q_N^2 = Q_N$ (Riesz idempotency) and L-invariance of range(Q_N). The Cauchy integral on a circle $\Gamma = \{|z| = \rho\}$ in the eigenvalue gap $|\lambda_{N+1}| < \rho < |\lambda_N|$ bounds the operator factor:

$$\|Q_N L^n\| = \left\| \frac{1}{2\pi i} \oint_\Gamma z^n R_{L_r}(z)\, dz \right\| \le \rho^{n+1} \cdot M_\infty,$$

where $M_\infty = \sup_{z\in\Gamma} \|R_{L_r}(z)\|$ is obtained via the resolvent bridge. The tail projection $\|Q_N\mathbf{1}\|_2 = \|\mathbf{1} - \sum_{j=1}^{N} P_j\mathbf{1}\|_2$ is computed directly from the rigorous spectral coefficients.

The combined bound is:

$$\boxed{\|R_N(n)\|_2 \le \rho^{n+1} \cdot M_\infty \cdot \|Q_N\mathbf{1}\|_2.}$$

Tail bound at $N = 50$. Using all $N = 50$ certified eigenvalues, the separating contour Γ lies in the eigenvalue gap $|\lambda_{51}| < \rho < |\lambda_{50}|$, with $|\lambda_{50}| \approx 1.47 \times 10^{-21}$ and $|\lambda_{51}| \approx 5.60 \times 10^{-22}$. The resolvent on this circle is certified via the block Schur method from the ordered Schur form at $K = 256$ (Phase 3 of the full certification pipeline). The tail projection $Q_{50}\mathbf{1}$ is computed at $K = 512$ (1024-bit precision) using the certified $\ell_j(\mathbf{1})$ and Schur eigenvectors; the correction for the infinite-dimensional lift ($N \cdot \varepsilon_{512}/\mathrm{sep}_{\min} \approx 4.37 \times 10^{-68}$) is negligible compared to the Galerkin norm.

Table 7: Tail bound parameters for the spectral remainder $R_{50}(n)$. Resolvent certified at $K = 256$; tail projection $\|Q_{50}\mathbf{1}\|$ computed at $K = 512$.

Parameter	Value
$\lvert\lambda_{50}\rvert$	1.468398×10^{-21}
$\lvert\lambda_{51}\rvert$	5.600685×10^{-22}
Circle radius ρ	1.014211×10^{-21}
$M_\infty = \|R_{L_r}\|$ on Γ	6.0617×10^{41}
$\|Q_{50}\mathbf{1}\|_2$	6.1383×10^{-21}
Prefactor $C = M_\infty \cdot \|Q_{50}\mathbf{1}\|$	3.7208×10^{21}

Comparison with $N = 20$. For comparison, the tail bound at $N = 20$ (resolvent certified at $K = 64$, tail projection at $K = 256$) gives $\rho_{20} = 3.81\times10^{-9}$, $M_\infty = 3.61\times10^{9}$, $\|Q_{20}\mathbf{1}\| = 3.64\times10^{-1}$, and prefactor $C_{20} = 1.32 \times 10^{9}$. The $N = 50$ tail circle is 10^{12} times smaller in radius, yielding bounds that are stronger by a factor of $\sim 10^{12(n+1)}$.

Table 8: Rigorous upper bounds on $\|R_{50}(n)\|_2 \le \rho^{n+1} \cdot M_\infty \cdot \|Q_{50}\mathbf{1}\|_2$.

n	$\|R_{50}(n)\|_2 \le$
1	$< 10^{-20}$
2	$< 10^{-41}$
5	$< 10^{-104}$
10	$< 10^{-209}$
20	$< 10^{-419}$
50	$< 10^{-1049}$
100	$< 10^{-2099}$

Integrated Spectral Expansion

The tail bound provides a rigorous L^∞ certificate for the integrated spectral expansion. Define

$$F_n^{(j_0)}(x) \;=\; \int_0^x \sum_{j=j_0}^{N} \lambda_j^n \, \ell_j(\mathbf{1}) \, v_j(t) \, dt,$$

which represents the contribution of modes $j \ge j_0$ to the antiderivative of $L^n\mathbf{1}$. For $j_0 = 2$, this measures the integrated deviation of $L^n\mathbf{1}$ from its equilibrium $\ell_1(\mathbf{1})\, v_1$. Removing additional dominant eigenfunctions reveals progressively finer structure linked to the Gauss map's Markov partition.

The integration $\int_0^x$ can be computed exactly in the shifted monomial basis: $\int_0^x (t-1)^k \, dt = ((x-1)^{k+1} - (-1)^{k+1})/(k+1)$. The L^∞ error bound follows from Cauchy–Schwarz and the Gram matrix of the shifted monomial basis $\{(x-1)^k\}$ on $[0,1]$ (whose spectral norm equals that of the Hilbert matrix, $\le \pi$):

$$\left| F_n^{(j_0)}(x) - \int_0^x \Big(L^n\mathbf{1}(t) - \sum_{j=1}^{j_0-1} \lambda_j^n \, P_j\mathbf{1}(t) \Big) dt \right| \;\le\; \sqrt{\pi}\, \|R_N(n)\|_2 \;\le\; \sqrt{\pi}\, \rho^{n+1} \cdot C.$$

Table 9: Signal amplitude $\max_x |F_n^{(j_0)}(x)|$ by mode cutoff j_0 and iterate n, with rigorous L^∞ error bounds.

j_0	Dominant λ_{j_0}	$n=1$	$n=2$	$n=5$
2	-0.3037	3.0×10^{-2}	8.7×10^{-3}	2.5×10^{-4}
3	0.1009	1.8×10^{-3}	1.7×10^{-4}	1.8×10^{-7}
4	-0.0355	1.6×10^{-4}	5.0×10^{-6}	2.3×10^{-10}
5	0.0128	1.6×10^{-5}	1.8×10^{-7}	4.0×10^{-13}
6	-0.0047	1.8×10^{-6}	7.2×10^{-9}	7.9×10^{-16}
L^∞ error bound		$\le 10^{-21}$	$\le 10^{-42}$	$\le 10^{-105}$

Figure 14 shows $F_n^{(j_0)}$ for $j_0 = 2, \ldots, 6$ and $n = 1, 2, 5$. As more dominant eigenfunctions are removed, the Markov partition structure of the Gauss map becomes increasingly visible: for $j_0 \ge 4$, the peaks of $F_n^{(j_0)}$ concentrate near $x \approx 1/k$, reflecting the cylinder boundaries $I_k = [1/(k+1), 1/k]$. The amplitude decreases by roughly a factor of $|\lambda_{j_0}/\lambda_{j_0-1}| \approx 1/3$ per removed mode. Even at the

smallest amplitudes ($\sim 10^{-16}$ for $j_0 = 6$, $n = 5$), the L^∞ error bound ($\leq 10^{-105}$) remains more than 80 orders of magnitude below the signal, confirming that the plotted curves are rigorous to plotting accuracy.

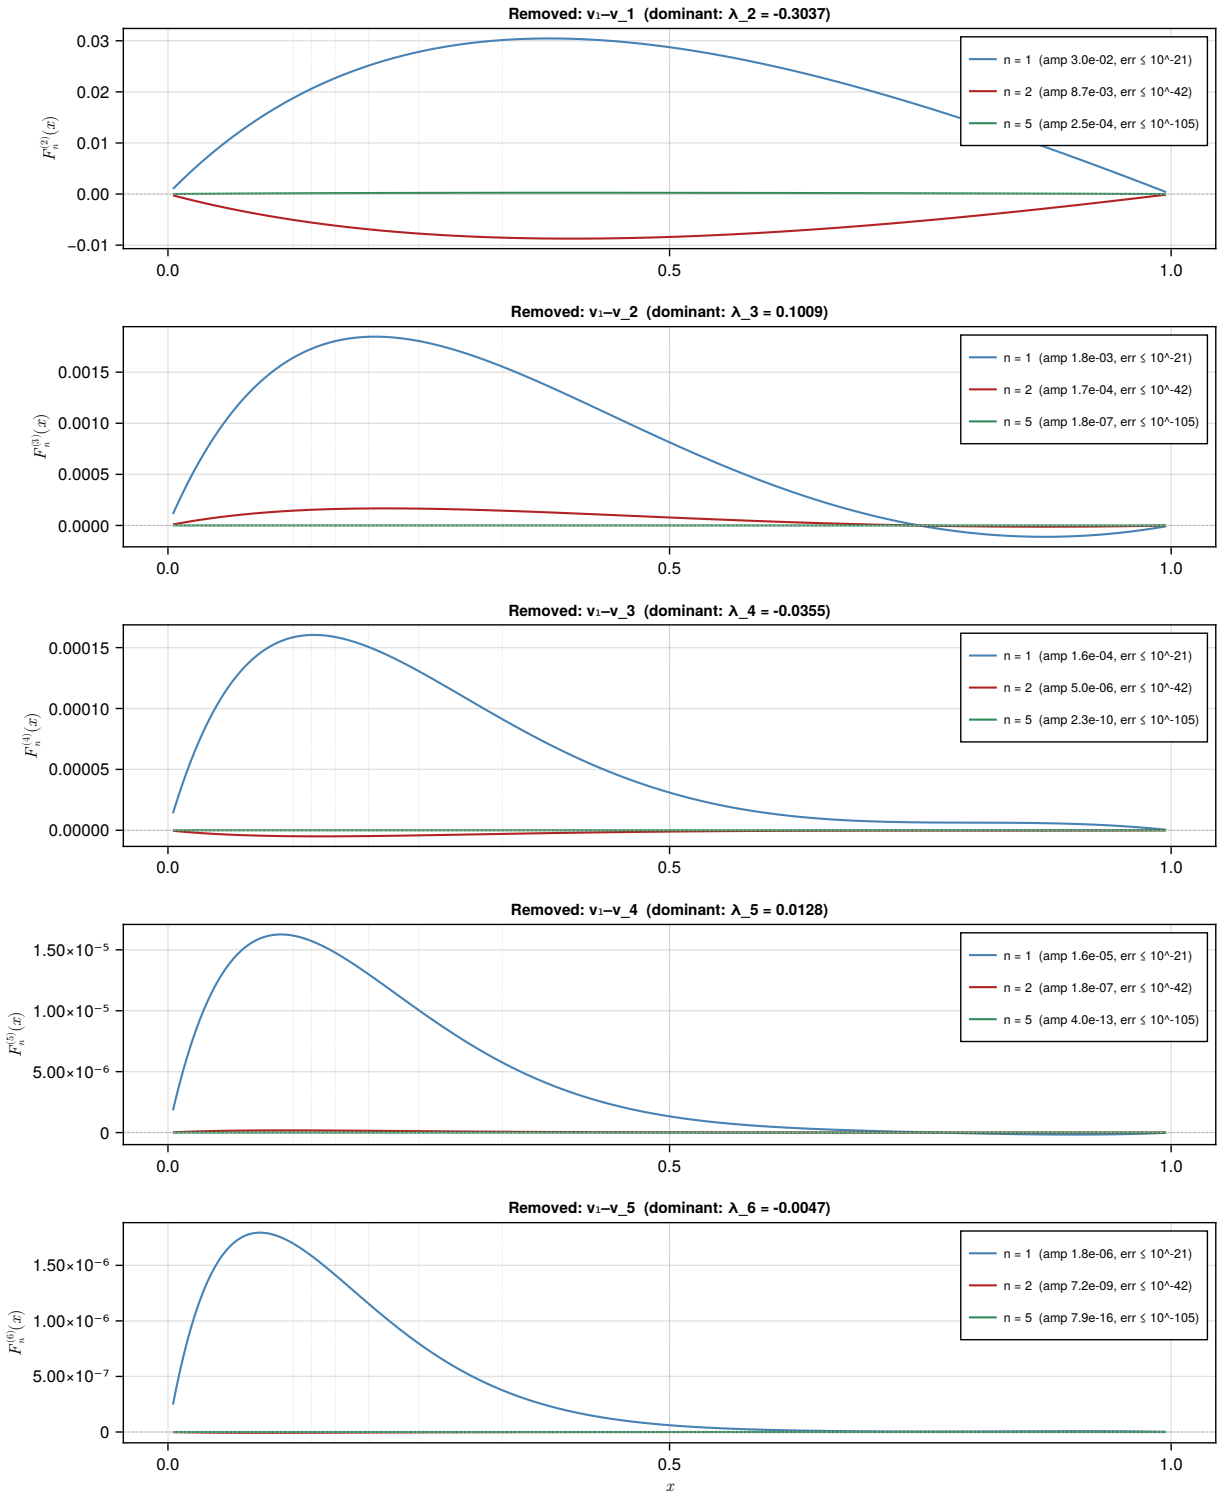

Figure 14: Integrated spectral expansion $F_n^{(j_0)}(x) = \int_0^x \sum_{j \geq j_0} \lambda_j^n \, \ell_j(\mathbf{1}) \, v_j(t) \, dt$ with the first $j_0 - 1$ eigenfunctions cumulatively removed. Each panel shows $n = 1$ (blue), $n = 2$ (red), $n = 5$ (green). Dotted vertical lines mark the Markov partition boundaries $x = 1/k$.

Eigenfunction Structure and the Markov Partition

The Gauss map $G(x) = \{1/x\}$ admits a countable Markov partition into cylinders $I_n = [1/(n+1), 1/n]$ for $n = 1, 2, 3, \ldots$. We investigate the relationship between the eigenfunctions v_j and this partition by analysing zero crossings and local extrema.

Zero crossings. The invariant density v_1 is strictly positive on $(0, 1)$, as expected. For $j \geq 2$, the eigenfunction v_j has a small number of zero crossings: odd-indexed eigenfunctions typically have 2 zeros, even-indexed have 1 or 3. The first zero of v_j sits near $x \approx 1/j$, matching the left endpoint of the cylinder I_{j-1}. For $j \gtrsim 40$, the polynomial representation in the shifted monomial basis $\{(x-1)^k\}$ develops spurious Runge-type oscillations at Float64 precision, producing artificially many zero crossings (e.g., ~ 2900 for v_{50}).

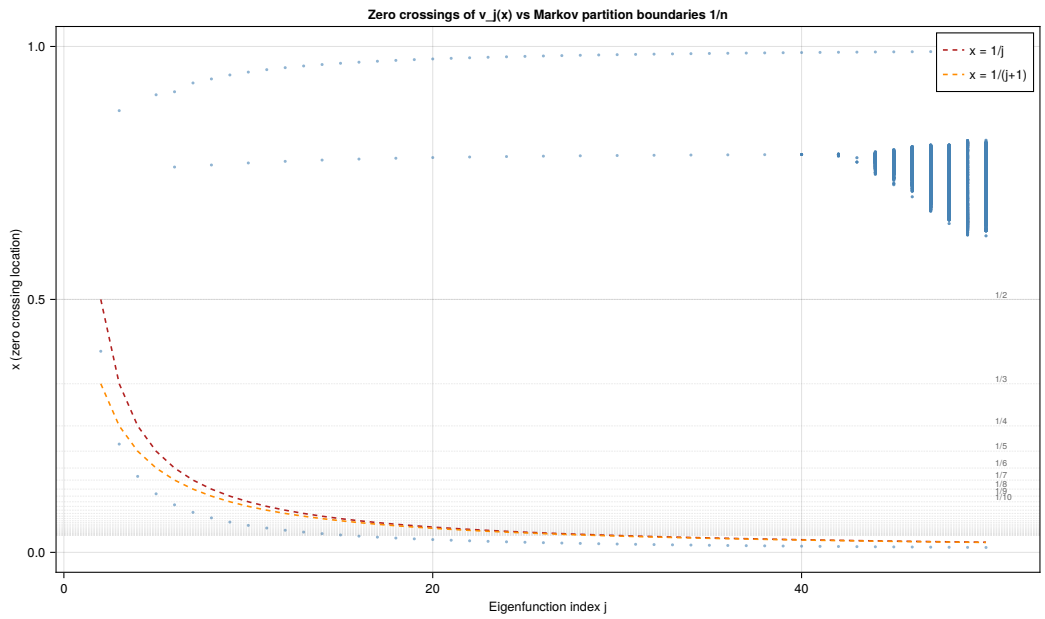

Figure 15: Zero crossing locations of $v_j(x)$ (blue dots) versus Markov partition boundaries $x = 1/n$ (dotted grey). The reference curves $x = 1/j$ (red dashed) and $x = 1/(j+1)$ (orange dashed) are shown.

Dominant local extremum. For each $j \geq 3$, the largest local extremum (in absolute value) of v_j is located near the Markov boundary $x = 1/j$:

$$x_{\max}(v_j) \approx \frac{1}{j}.$$

For $j = 3, \ldots, 24$, the extremum lies slightly above $1/j$, inside $I_{j-1} = [1/j, 1/(j-1)]$; for $j \geq 25$, it drifts slightly below $1/j$, into $I_j = [1/(j+1), 1/j]$. The relative error $|x_{\max}(v_j) - 1/j|/(1/j)$ is tabulated below for selected j:

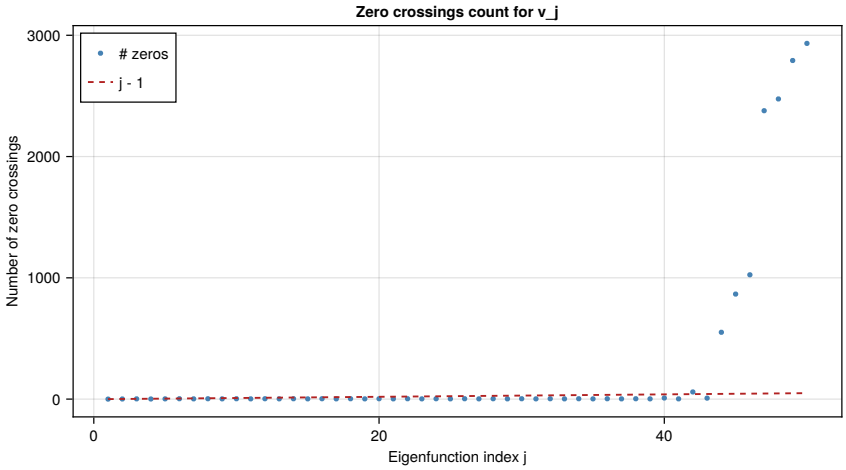

Figure 16: Number of zero crossings of v_j versus j. For $j \leq 39$ the count stays at 1–3; the explosion for $j \geq 40$ is a Runge artefact of the polynomial basis at Float64 precision.

j	$x_{\max}(v_j)$	$1/j$	rel. error	cylinder
3	0.45498	0.33333	36.5%	I_2
5	0.23258	0.20000	16.3%	I_4
10	0.10663	0.10000	6.6%	I_9
20	0.05056	0.05000	1.1%	I_{19}
30	0.03296	0.03333	1.1%	I_{30}
40	0.02439	0.02500	2.4%	I_{40}
50	0.01932	0.02000	3.4%	I_{51}

For $j \geq 10$ the mean relative error is 2.3% (std. dev. 1.5%); for $j \geq 20$ it is 1.8% (std. dev. 1.1%). Each eigenfunction is thus "tuned" to the Markov boundary $x = 1/j$, confirming that higher eigenmodes encode progressively finer partition structure.

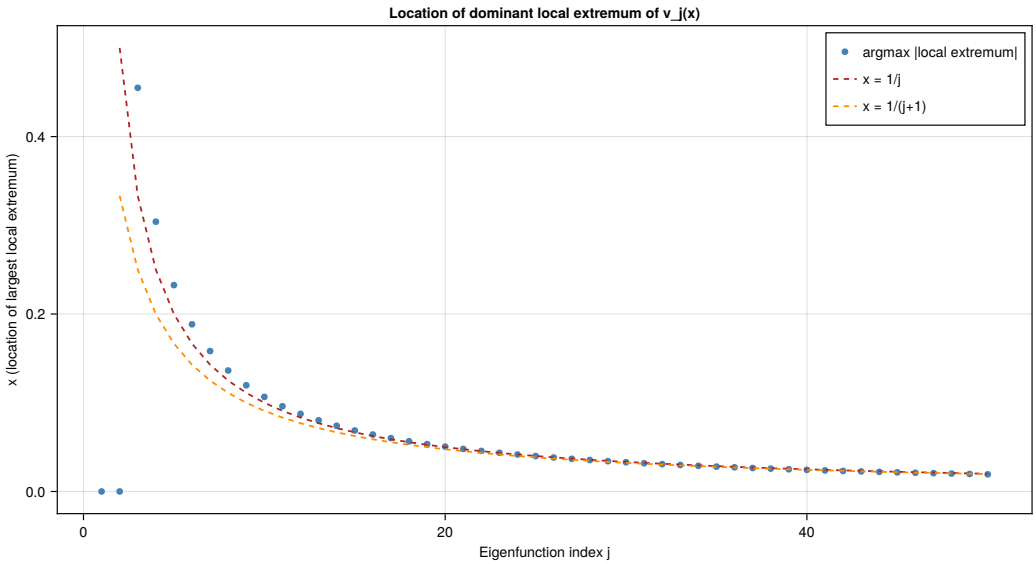

Figure 17: Location of the dominant local extremum of $v_j(x)$ (blue dots) compared with $x = 1/j$ (red dashed) and $x = 1/(j+1)$ (orange dashed). For $j \geq 10$ the extremum tracks $1/j$ with $\sim 2\%$ relative error.

Non-Normality of the Transfer Operator

The GKW transfer operator is not normal, so its Schur decomposition $A = QTQ^*$ has a non-trivial strictly upper triangular part. We quantify this non-normality using the ordered Schur form with eigenvalues sorted by decreasing $|\lambda_j|$ on the diagonal ($K = 512$, $n = 513$).

Henrici departure from normality. The Henrici number

$$\delta_H \;=\; \frac{\|T - \mathrm{diag}(T)\|_F}{\|T\|_F} \;=\; 3.82 \times 10^{-1}$$

indicates that roughly 38% of the Frobenius norm of T resides in the off-diagonal entries, confirming significant non-normality.

Coupling structure. For fixed row i, the entry T_{ij} with $j > i$ quantifies the coupling from Schur mode j (smaller $|\lambda_j|$) back into mode i (larger $|\lambda_i|$). Figure 18 shows the full 80×80 heatmap of $\log_{10} |T_{ij}|$; Figure 19 displays the row profiles $|T_{i,j}|$ for selected i.

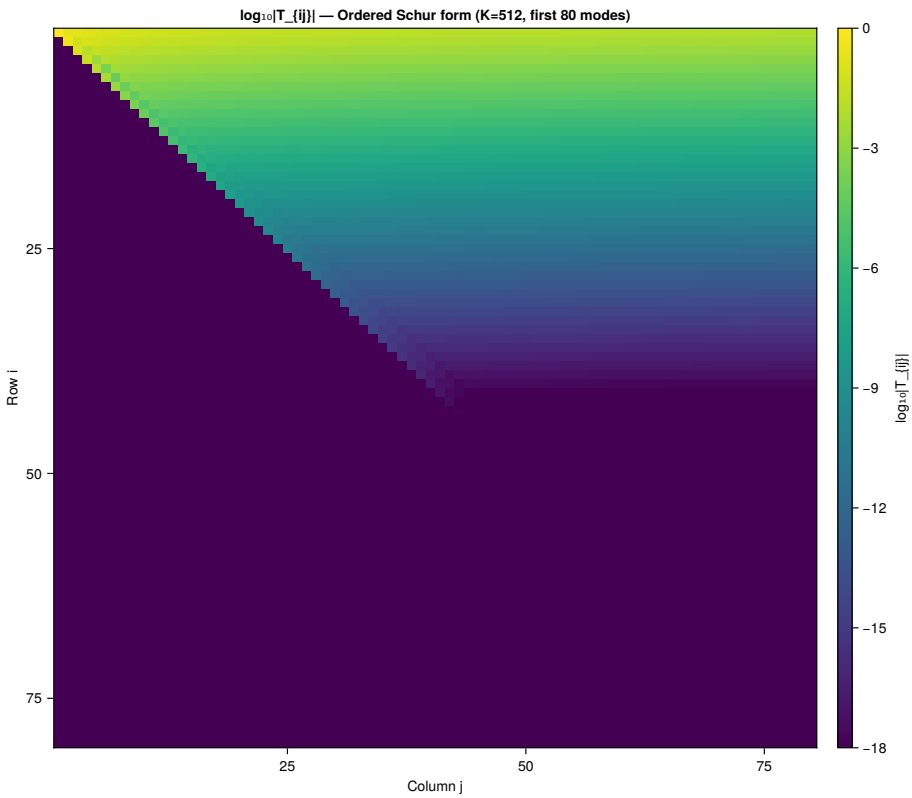

Figure 18: Heatmap of $\log_{10} |T_{ij}|$ in the ordered Schur form (eigenvalues sorted by decreasing $|\lambda|$, first 80 modes). The diagonal contains the eigenvalues; the upper triangular entries encode non-normal coupling between modes.

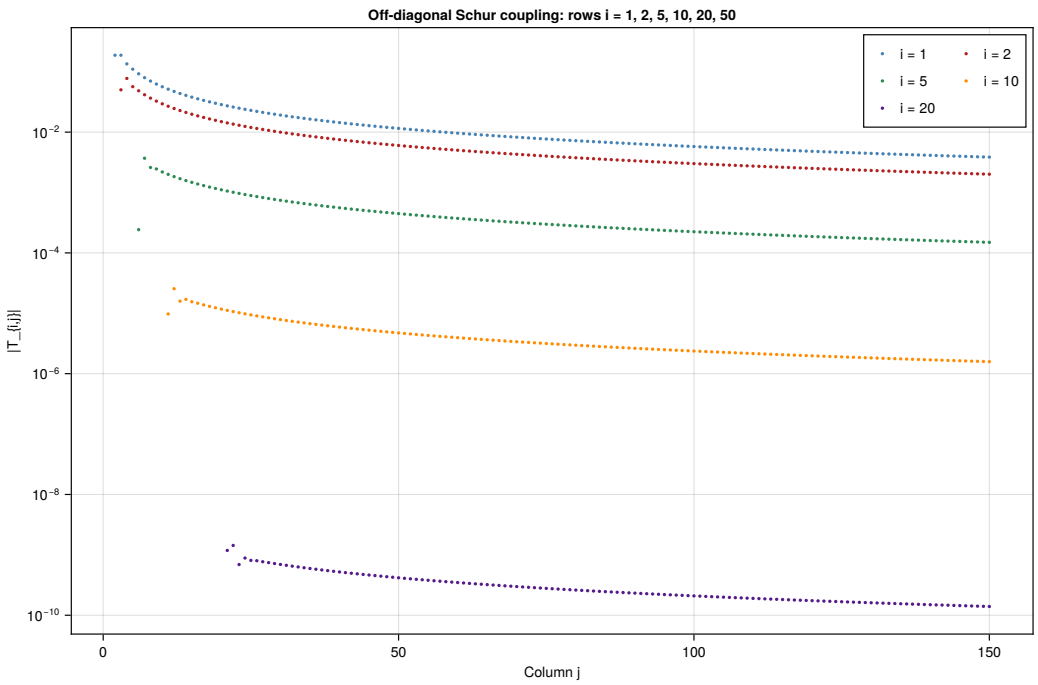

Figure 19: Off-diagonal Schur coupling $|T_{i,j}|$ for rows $i = 1, 2, 5, 10, 20, 50$ (log scale). Mode j feeds back into mode i with strength $|T_{i,j}|$.

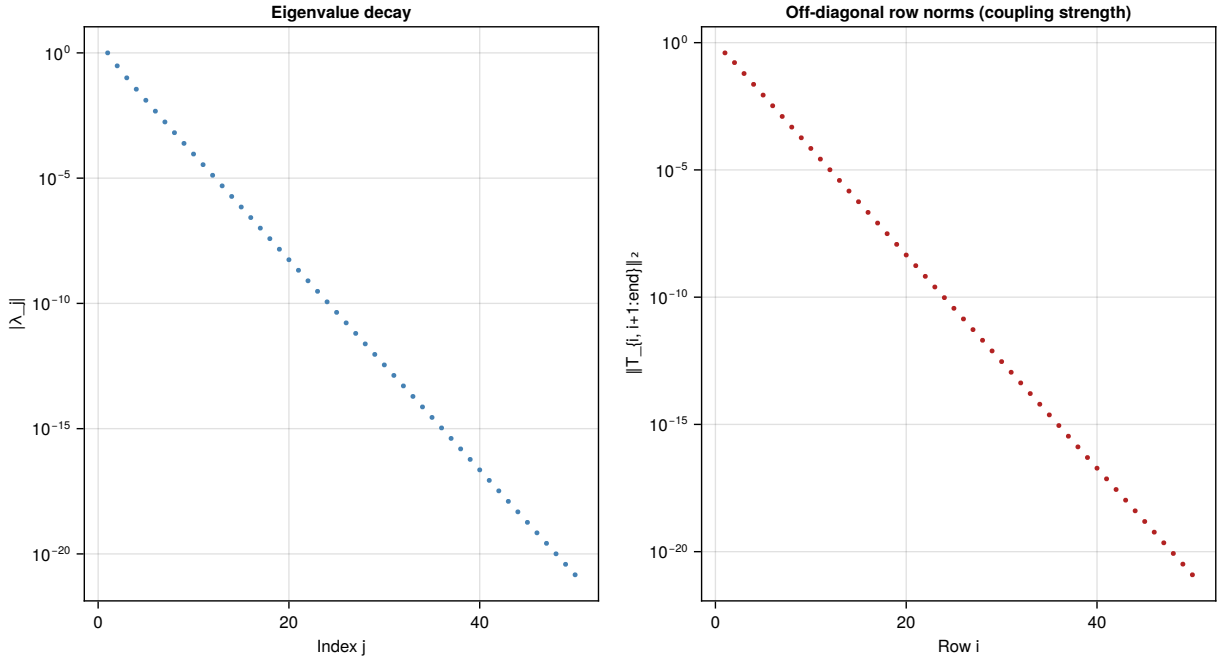

Figure 20: Left: eigenvalue decay $|\lambda_j|$ versus index j. Right: off-diagonal row norms $\|T_{i,i+1:n}\|_2$ measuring the total coupling strength from all higher modes into mode i.
